How does web hosting work

Web hosting happens when the files that make up a website are uploaded from a local computer on to a web server. The server's resources, (RAM, hard drive space, and bandwidth) are allocated to the websites using it.

The division of server resources varies depending on the type of hosting plan chosen. To choose the appropriate hosting plan, you first need to differentiate between the plans available. This doesn't have to be complicated. For the non-technical readers, let's use a simple analogy: Choosing web hosting is similar to searching for office space:

How do you decide which type of office space is right for your needs? Is a workstation in an open co-working space enough, or the next best thing; an office within a business center. Do you have intentions to expand quickly or expect a lot of people coming and going? Would you consider renting an entire building or would building your own space appeal?

Aside from the style of office you use there are other considerations. How easy the rooms are to access, which functions they offer (extras such as a whiteboard, high-speed internet, and other facilities), and where are they located and the overall cost. These considerations will determine your needs and help decide which type of office is right for you. Let's compare this selection process to deciding which web hosting fits.

Shared hosting is similar to renting a workstation in a busy, noisy, open plan office or co-working space. You have all the modern conveniences: a desk, internet connection and some stationary and you share the space with other co-workers including the kitchen, printer, and restroom. You can't do any makeovers to the space such as installing whiteboards etc. This is a popular option for launching small websites and not appropriate for large-scale commercial projects.

A virtual private server (VPS) is a nice step up from shared hosting. Medium sized business will benefit from renting an office within a business park. With a VPS, users are isolated from each other. You have neighbors, but you are less dependant on them, and you can carry out any makeovers (customizations) as you like and organize your workstation on your own.

Using an entire office building is comparable to hosting on a dedicated server. It's a more expensive option and best for websites who value reliability and high performance. Since you control the entire space, you have more say over configurations and plenty of space, but it's not worth investing in if you won't use the space included.

We'll discuss each type of hosting in greater detail later in the article.

We'll discuss each type of hosting in greater detail later in the article. Web hosting and domain hosting
Once you've purchased a domain name, the files that hold your website's content (HTML, CSS, images, databases, etc.) need to be stored together in a location connected to the internet — a web server. Once the website's files are uploaded to a hosting company's web server, the host is then responsible for delivering the files to users.

We've mentioned that hosting makes websites available for people to visit through their web browser, but how does that work exactly? The domain name system (DNS) makes sure that website browser connects to the right computer (server) that stores your website files.
